In a right triangle, the square of the length of the hypotenuse is equal to the sum of the squares of the lengths of the other two sides. For example, a triangle with sides of lengths 4, 5, and 3 units is a right triangle because $5^2 (25) = 3^2 (9) + 4^2 (16)$.

Write a program that prompts for the lengths of the three sides of a triangle and prints an appropriate message saying whether the triangle is a right triangle or not. You may not assume the sides are entered in any particular order, but you may assume the sides would make a triangle (the sum of the lengths of two sides will be greater than the length of the third side). You may assume all sides have whole number lengths (integer lengths greater than 0).

Test with 3, 4, 5; 5, 4, 3; 4, 5, 3; 6, 10, 8; 4, 4, 6; and several other sets of lengths of your own choice, both forming a right triangle and not forming a right triangle. Check a few by hand and include the math in a little text file submitted with your program and output files.

Use three separate if() statements for the "is-it-a-right-triangle" tests, on for each possible hypotenuse. Remember if you don't find a right triangle for a fourth if() statement printing a message saying the sides don't form a right triangle.

You may not use if-else() for this program. For the fourth if() test, you MAY NOT just test "is it not a right triangle" by using the squares of the sides again.

You may have only one return 0; statement, at the bottom of main().
